On functional central limit theorems for dependent, heterogeneous arrays with applications to tail index and tail dependence estimation

Jonathan B. Hill

Department of Economics, University of North Carolina, CB 3305, Chapel Hill, NC 27599-3305, USA

ABSTRACT

We establish invariance principles for a large class of dependent, heterogeneous arrays. The theory equally covers conventional arrays, and inherently degenerate tail arrays popularly encountered in the extreme value theory literature including sample means and covariances of tail events and exceedances. For tail arrays we trim dependence assumptions down to a minimum leaving non-extremes and joint distributions unrestricted, covering geometrically ergodic, mixing, and mixingale processes, in particular linear and nonlinear distributed lags with long or short memory, linear and nonlinear GARCH, and stochastic volatility. Of practical importance the limit theory can be used to characterize the functional limit distributions of a tail index estimator, the tail quantile process, and a bivariate extremal dependence estimator under substantially general conditions.

1. Introduction

In this paper we deliver invariance principles for $L_r$-bounded stochastic functions, including conventional arrays and inherently degenerate tail arrays, allowing significant degrees of dependence and heterogeneity. The tail array results permit the most general available limit theory for Hill’s (1975) tail index estimator, a tail empirical quantile processes, and a tail dependence estimator. Together, these results have substantial practical value: extreme value estimators are frequently applied to dependent and/or heterogeneous data in finance and macroeconomics, yet available theory does not adequately cover many processes assumed in the literature (e.g. stationary ARFIMA; nonlinear GARCH processes; regime switching).

We present invariance principles of the form

$$\sum_{\ell=1}^{n(z)} X_{n,\ell}(u) \Rightarrow X(\zeta, u) \quad \text{where } \zeta \in [0,1] \text{ and } u \in [0,1]^{k-1}, \quad k \geq 1.$$
for mean-zero functional arrays \((X_{n,t}(u)), X_{n,t}: [0,1] \to \mathbb{R}\), with \(X(\xi, u)\) a Gaussian process with almost surely continuous sample paths, and \(n(\xi)\) an integer sequence. The array \((X_{n,t}(u))\) is assumed to be uniformly \(L_r\)-bounded

\[
\sup_{u \in [0,1]^2} (E|X_{n,t}(u)|^r)^{1/r} = O(n^{-a(r)}) \quad (1)
\]

for some mapping \(a : [1, \infty) \to (0, \frac{1}{2}]\) and \(r \geq 2\). The standard array for a stationary finite variance process \((X_t)\) is

\[
X_{n,t} = n^{-1/2}[X_t - E[X_t]] / [E(n^{-1/2} \sum_{r=1}^n (X_t - E[X_t])^2)^{1/2}].
\]

hence \(k = 1\) and \(a(r) = \frac{1}{2}\) at least for \(r \in [1, 2]\).

The main invariance principle, Theorem 2.1, equally covers near epoch dependent (NED) arrays and extremal-NED tail arrays, including the sample means and covariances of tail events and exceedances (Corollary 3.3). The NED concept dates in various forms at least to Ibragimov (1962), Ibragimov and Linnik (1971), and McLeish (1975). See Gallant and White (1988) and Davidson (1994) for historical details. E-NED, due to Hill (2005), restricts NED to extremes only, it is a marginal tail property that leaves non-extremes and joint distributions unrestricted, and characterizes at least linear and nonlinear distributed lags with long or short memory, linear and nonlinear GARCH and stochastic volatility. See Section 3.

Consider some process \((X_t)\) that takes values on \([\infty, 0)\), where \([X_t]_{n,t}^i\) is the sample path, and \(k_n\) and \(b_n\) are real-valued sequences satisfying \(k_n \in \mathbb{N}, k_n \to \infty, k_n/n \to 0, b_n \to \infty\) and \(n/k_n\) \((X_t > b_n) \to 1\) as \(n \to \infty\). Thus, \(b_n\) is the asymptotic \(k_n/n\)th to 0 quantile and any \(X_t \geq b_n\) is an extreme value.

Tail arrays include the \(b_n\)-event process

\[
U_{n,t}(u) := k_n^{-1/2}[(X_t > b_n/u) - P(X_t > b_n/u)], \quad u \in [0,1],
\]

the \(b_n\)-exceedance process

\[
U_{n,t} := k_n^{-1/2}[(\ln X_t/b_n) - E[(\ln X_t/b_n)]],
\]

and an intermediate tail empirical quantile processes,

\[
q_k := k_n^{-1/2} \times \ln[X_{k(n)}/b_n]\quad \text{where} \quad X_{(1)} > X_{(2)} \geq \ldots \text{are ranked } X_t's.
\]

The tail array \((U_{n,t}(u))\) is a uniformly bounded function of a possibly infinite variance process. Central limit theorems for bounded functions of \(\alpha\)-stable moving averages are delivered in Hsing (1999), Pipiras and Taqqu (2003), and Pipiras et al. (2007). Property (1) does not require boundedness of \(X_{n,t}(u)\), and the process \(X_t\) on which \(X_{n,t}(u)\) is based extends well beyond moving averages, the \(\alpha\)-stable laws and their domains of attraction.

Our motivation is the use of tail arrays for tail shape and dependence characterization and estimation. We deliver an invariance principle for the \(k_n\)-th-exceedance mean

\[
\hat{x}_{k_n}^{-1}(\xi) := \frac{1}{k_n} \sum_{t=1}^{n(\xi)} \{\ln X_t/X_{(k_n(\xi)+1)}\}_+, \quad (5)
\]

a functional estimator of the index of regular variation proposed by Hill (1975) and a natural measure of tail thickness (Resnick, 1987) and therefore financial market risk (Bradley and Taqqu, 2003). The limit theory is apparently the most general available.

Similarly, we prove an invariance principle for the extremal event covariance

\[
\hat{\rho}_{n,\xi}(h,u) = \sum_{t=1}^{n(\xi)} U_{n,t-1-H}(u_1) \times U_{n,t}(u_2), \quad u = [u_1, u_2]' \in [0,1]^2
\]

(6)
for a joint process \( \{X_{t_1}, X_{t_2}\} \) where \( U_{n,t}(u_i) \) is defined by (2) for each \( X_{t_i} \). We do not require a specified bivariate tail shape and we allow for any form of non-extremal dependence, all in contrary to extant conventions. Cf. Ledford and Tawn (1997, 2003), Coles et al. (1999), Embrechts et al. (2003), Heffernan and Tawn (2004), Schmidt and Stadtmüller (2006) and Klüppelberg et al. (2007).

Section 2 contains the main result for \( \{X_n(u)\} \), Section 3 delivers invariance principles for tail arrays \( \{U_{n,t}, U_{n,t}(u)\} \). Section 4 presents examples, and Section 5 characterizes limit laws for \( \tilde{X}_{n}^{-1}(\xi), q_{kn} \) and \( \hat{\rho}(\xi, u) \). All proofs are relegated to Appendix A.1, and Appendix A.2 contains supporting lemmata.

Throughout \( \mathbb{P} \) and \( \mathbb{D} \), respectively, denote convergence in probability and finite dimensional distributions, and \( \Rightarrow \) denotes weak convergence on a metric space. Gaussian elements of function spaces have zero means. \( |z| \) is the integer part of \( z \). Write \( (z)_+ := \max\{0, z\} \). \( \cdot \) denotes the \( l_1 \)-matrix norm: \( |x| := \sum |x_{ij}| \), and \( \| \cdot \|_p \) is the usual \( L_p \)-matrix norm: \( \|x\|_p := (\sum E|X_{ij}|^p)^{1/p} \). \( K > 0 \) is always a finite constant whose value may change from line to line. Write \( \sigma_n := \sigma(X_n : n \geq 1) \).

2. Assumptions and main result

Let \( \{X_t : \tau < t < \infty\} \) be a stochastic process on the probability measure space \((\Omega, \mathcal{F}, \mu)\), where \( \mathcal{F} = \sigma(\bigcup_{t \in \mathbb{Z}} \mathcal{F}_t) \) and \( \mathcal{F}_{t-1} \subset \mathcal{F} = \sigma(X_t : \tau \leq t) \).

2.1. Cadlag processes

We will work with processes \( x(\xi, u) \) on the following cadlag space (consult Billingsley, 1999)
\[
D_{k} := D([\xi, 1] \times [0, 1]^{k-1}), \quad k \geq 1,
\]
where \( \xi \in (0, 1), u \in [0, 1]^{k-1} \), and \( x(1, u) = x(1-u, u) \) for every element \( x \in D_{k} \). If \( k = 1 \) then by convention \( x(\xi, u) = x(\xi) \). The martingale difference approximation argument used to prove the main result, Theorem 2.1, is greatly expedited by bounding \( \xi \) away from zero.

Let \( X_{n,t}(u) \) be \( D([0, 1]^{k-1}) \)-valued and define
\[
X_{n}(\xi, u) := \sum_{i=1}^{n(\xi)} X_{n,i}(u).
\]
The functional \( n : [0, 1] \rightarrow \mathbb{N} \) is right continuous with left limits, non-decreasing, \( n(\xi) \rightarrow \infty \) as \( n \rightarrow \infty \), \( n(\xi_1) - n(\xi_2) \rightarrow \infty \) \( \forall \xi_1 > \xi_2 \), \( n(0) = 0 \), and \( n(1) = n(1) \leq n \).

We assume \( \{X_n(u)\} \) is \( L_r \)-bounded in the sense of (1). Examples in the extreme value theory literature are detailed in Section 3.

Definition (Functional array). \( \{X_n(u)\} \) is an \( L_r \)-functional array of \( \{X_t\} \) if (i) \( X_{n,t}(u) \in D([0, 1]^{k-1}) \); (ii) \( E[X_{n,t}(u)] = 0 \); and (iii) there exists a function \( a : [1, \infty) \rightarrow (0, \frac{1}{2}] \), such that \( \sup_{n \in [0,1]^{k-1}, t \geq 1} \|X_{n,t}(u)\|_r = O(n^{-a(r)}) \) for some \( r \geq 2 \).

Remark 1. We call \( a(r) \) the \( r \)-th moment index.

Remark 2. The standard case \( X_{n,t} = n^{-1/2}(X_t - E[X_t])\|n^{-1/2} \sum_{t=1}^{n}(X_t - E[X_t])\|_2 \) where \( \sup_{t \geq 1} \|X_t \|_2 < \infty \), implies \( a(2) = 2 \) for at least \( r \in [1, 2] \).

Remark 3. Although \( L_r \)-boundedness \( \|X_{n,t}(u)\|_r \leq Kn^{-a(r)} \) uniformly in \( t \) is inherently satisfied for tail arrays \( \{U_{n,t}(u), U_{n,t}(u)\} \) under minimal assumptions, it does limit the scope of the main results for non-stationary non-degenerate arrays (cf. de Jong, 1997; Davidson and de Jong, 2000; Wu and Min, 2005).

2.2. F-mixing and F-NED: tail memory and heterogeneity

The following dependence concepts are developed in Hill (2005) for a less general context. Let \( \{t_i\} \) be an arbitrary, possibly vector-valued stochastic process with \( \sigma \)-algebra
\[
\mathcal{G}_t := \sigma(t_i : \tau \leq t) \quad \text{where} \quad \mathcal{G}_0 := \sigma(t_i : a \leq t \leq b).
\]
In some minimal sense we want to be able to predict \( X_{n,t}(u) \) using \( \mathcal{G}_t \)-measurable information \( E_{n,t} \) induced from \( t_i \). Examples include \( E_{n,t} = t_i \) itself, or \( E_{n,t} = h(t_i, t_{i-1}, \ldots) \) a Borel measurable function; but also the extreme event \( E_{n,t} = l(|t_i| > \pi_{n,t}) \), exceedance \( (|t_i| - \pi_{n,t}) \), and value \( |t_i| \times l(|t_i| > \pi_{n,t}) \) for some non-stochastic array \( \{\pi_{n,t}\} \), \( \pi_{n,t} \rightarrow \infty \) as \( n \rightarrow \infty \), or Borel measurable functions of extreme values.
Typically $E_{n,t} = \varepsilon_t$ is iid or a martingale difference. The point here is we only require $\varepsilon_t$ to satisfy a weak mixing condition in the sense that the $G_t$-measurable information $E_{n,t}$ is assumed to mix. Throughout we use the following array of $\sigma$-fields:

$$F_{n,t} := \sigma(E_{n,t} : t \leq t) \quad \text{where} \quad F^i_{n,t} := \sigma(E_{n,t} : s \leq t \leq t)$$

and a sequence $\{l_n\}$ of integer displacements where $l_n \to \infty$ as $n \to \infty$. Define $\sigma$-sub-fields $A_{n,t} \in F^i_{n,\infty}$ and $B_{n,t+l_n} \in F^i_{n,t+l_n}$, and define mixing coefficients

$$\alpha_n \equiv \sup_{A_{n,t}B_{n,t+l_n} \subseteq Z} |P(A_{n,t} \cap B_{n,t+l_n}) - P(A_{n,t})P(B_{n,t+l_n})|,$$

$$\sigma_n \equiv \sup_{A_{n,t}B_{n,t+l_n} \subseteq Z} |P(B_{n,t+l_n} | A_{n,t}) - P(B_{n,t+l_n})|.$$

**Definition (F-mixing).** If $n^{1/2 - a(r)}|2^{l_n}|^{1/p} \alpha_n \to 0$ as $n \to \infty$ for some $\{l_n\}$, $l_n \to \infty$, and some $r \geq 2$ and $\lambda > 0$ we say $\{\varepsilon_t\}$ is *functional-strong mixing with size $\lambda$*. If $n^{1/2 - a(r)}|2^{l_n}|^{1/p} \alpha_n \to 0$ as $n \to \infty$ for some $\{l_n\}$, $l_n \to \infty$, and some $r \geq 2$ and $\lambda > 0$ we say $\{\varepsilon_t\}$ is *functional-uniform mixing with size $\lambda$*.

**Remark.** F-mixing is simply mixing assigned to the functional $\{E_{n,t}\}$ as $n \to \infty$. Hill (2005), for example, exploits a mixing tail event $E_{n,t} = \{ |\varepsilon_t| > \pi_{n,t}\}$, $\pi_{n,t} \to \infty$ as $n \to \infty$, in which case $\varepsilon_t$ is called extremal-mixing (E-mixing). Standard inequalities apply, and if $\varepsilon_t$ is mixing then it is F-mixing. See Hill (2005) for a comparison of E-mixing and Leadbetter’s (1983) D-mixing property.

Next, we restrict tail memory and heterogeneity in $\{X_t\}$ by assuming the functional array $\{X_{n,t}(u)\}$ is NED. We say some stochastic array $\{\eta_{n,t}\}$ is $L_q$-NED, $p > 0$, on the array of $\sigma$-fields $\{F_{n,t}\}$ with size $\lambda > 0$ if there exist arrays of non-stochastic real numbers $\{d_{n,t}\}$ and $\{\phi_t\}$, where $d_{n,t} \geq 0$, $\phi_t \in [0, 1]$, and $\phi_t = o(1)^{-\lambda}$ such that

$$\|\eta_{n,t} - E[\eta_{n,t}|F_{n,t}^{t+1}]\|_p \leq d_{n,t} \times \phi_t.$$

As $l \to \infty$ information induced from the near epoch $\{E_{n,t}\}_{t=l}^{t+1}$ can be used to predict $y_{n,t}$ with vanishing prediction error in $L_p$-norm. The “constants” $d_{n,t}$ permit time dependence of the $L_p$-norm and may satisfy $d_{n,t} \to \infty$ as $t \to \infty$ if there exists a trending moment. The “coefficients” $\phi_t$ gauge hyperbolic (i.e. “long”) memory decay. If memory is geometric (i.e. “short”) $\phi_t = o(1)^{-\lambda}$, then size $\lambda$ is irrelevant and therefore arbitrarily large.

**Property (8)** characterizes linear and nonlinear distributed lags with any degree of tail thickness and long or short memory (e.g. bounded contraction mappings, bilinear processes; see Gallant and White, 1988; Davidson, 1994), covariance stationary GARCH (Davidson, 2004), and stochastic volatility (Hill, 2008a). Further, since $\varepsilon_t$ can in principle be anything, it can be a mixing process, and $y_{n,t} = E_{n,t} = \varepsilon_t$ is always possible. Thus, any mixing process, including geometrically ergodic processes, can be characterized by NED (8), including nonlinear GARCH (e.g. Carrasco and Chen, 2002), nonlinear AR-GARCH, neural networks and regime switching processes (e.g. Meitz and Saikkonen, 2008).

**Definition (Functional near epoch dependence).** $\{X_t\}$ is $L_q$-F-NED, $q \geq 1$, on $\{F_{n,t}\}$ with size $\lambda > 0$ if some $L_r$-functional-tail array $\{X_{n,t}(u)\}$ based on $\{X_t\}$ satisfies two conditions.

(i) For some $\{l_n\}$, $l_n \to \infty$,

$$\|X_{n,t}(u) - E[X_{n,t}(u)|F_{n,t}^{t+1}]\|_q \leq d_{n,t} \times \phi_n, \quad u \in [0, 1]^{k-1},$$

where the Lebesgue measurable array $\{d_{n,t}(u)\}$, $d_{n,t} : [0, 1]^{k-1} \to \mathbb{R}_+$, satisfies $\sup_{u \in [0,1]^{k-1}} 1 \geq 1 d_{n,t}(u) = O(n^{a(r)})$ for some $r \geq q$, and $\phi_n = o(n^{a(r)-a(q)})$. If $k = 1$ then $d_{n,t}(u) = d_{n,t}$.

(ii) For $\Delta X_{n,t}(u_1, u_2) := X_{n,t}(u_1) - X_{n,t}(u_2)$, and $u_1, u_2 \in [0, 1]^{k-1}$,

$$\|\Delta X_{n,t}(u_1, u_2) - E[\Delta X_{n,t}(u_1, u_2)|F_{n,t}^{t+1}]\|_q \leq \left(\frac{d_{n,t} \times \max_{1 \leq i < k-1} |u_{2,i} - u_{1,i}|^q}{\phi_n}\right) \times \phi_n,$$

where $\sup_{u_1, u_2} 1 \geq 1 d_{n,t} = O(n^{a(q)})$.

**Remark 4.** Property (9) simply states the functional array $\{X_{n,t}(u)\}$ is $L_q$-NED on $\{F_{n,t}\}$, and can therefore be predicted from information induced from the near epoch $\{E_{n,t}\}_{t=l}^{t+1}$ as $n \to \infty$. Since $d_{n,t}(u)\phi_n = o(n^{-a(q)})$ the scaled prediction error satisfies at least hyperbolic decay

$$n^{a(q)}\|X_{n,t}(u) - E[X_{n,t}(u)|F_{n,t}^{t+1}]\|_q = o(1)^{-\lambda}.$$
Remark 5. In the non-functional case $X_{nt} = X_{nt}(u)$ property (10) is irrelevant and (9) reduces to the $L_2$-NED property (8). Thus, $L_2$-F-NED easily captures the conventional $L_2$-NED setting for covariance stationary $X_{nt} = n^{-1/2}(X_t - E[X_t]) / \sqrt{n^{-1/2} \sum_{i=1}^n (X_i - E[X_i])^2}$, with $a(2) = 1/2$. In this case $n^{\alpha(2)} P_{X_t} - E[X_t] = o(n^{-1/2})$ with $\alpha(2) = 1/2$. Property (10) ensures the sequence of probability distributions associated with $(X_{nt}(\xi, u))$ is tight. In order to ensure the limit law $X(\xi, u)$ is also almost surely continuous in $u$ we will need a partial sum of $Z_{nt}(\delta) := \sup_{|u_1 - u_2| < \delta} |\Delta X_{nt}(u_1, u_2)|$ to have a bounded variance. This can be ensured by assuming $Z_{nt}(\delta)$ is $L_2$-NED, a much stronger version of (10). Under weak conditions (e.g. Dellacherie and Meyer, 1978) $Z_{nt}(\delta)$ is $o(\sum_{i=1}^n F^{-1/2}_{n-t, u_i} u_i)$ measurable for each $j = 1, \ldots, k - 1$, and the required extension of (10) is

$$
\|Z_{nt}(\delta) - E[Z_{nt}(\delta)] F^{-1/2}_{n-t, u_i} u_i \|_q \leq K \times \delta^{1/q} \times \bar{d}_{n,t} \times \varphi_{n,t}, \quad j = 1, \ldots, k - 1.
$$

2.3. Main result

Assumption 1. (a)$(X_{nt}(u))$ is an $L_r$-functional array with $r$th-moment index $a(r): a(2) = 1/2$ and $2a(2r) > a(r)$.

(b)$(X_t)$ is $L_2$-F-NED in the sense of (9) with size $\lambda = 1/2$. The base $\{u_t\}$ is F-strong mixing with size $\eta(r - 2)$ for some $r > 2$, or $F$-uniform mixing with size $\eta(2(r - 1))$ for some $r > 2$.

(c) $(X_t)$ is $L_2$-F-NED in the sense of (10) with size $\lambda = 1/2$, and the same mixing base $\{u_t\}$ as above.

(d) For some finite function $\kappa(\xi, \delta) \geq 1$ the limit $(n^{\alpha(\xi) + \delta/\eta(\xi)} - n^{\kappa(\xi, \delta)}) \to 0$ exists $\forall \xi \in [1 - \delta, \delta]$, $\delta \in [0, 1]$. $\xi$

Theorem 2.1. Under Assumption 1, $X_{nt}(\xi, u) \Rightarrow X(\xi, u)$ on $D_k$ where $X(\xi, u)$ is Gaussian with independent increments, $P(X(\xi, \cdot) \in C(\xi, 1)) = 1$ and $E(X_{nt}(\xi, u)^2) = O(1)$. Further, if (10) holds then $P(X(\cdot, u) \in C[0, 1]^{k-1}) = 1$.

Remark 6. The proof exploits a martingale difference approximation for NED $(X_{nt}(u))$ based on Bernstein blocks, cf. Davidson (1992), de Jong (1997) and Davidson and de Jong (2000). The restrictions on the $r$th-moment index $a(r)$ under Assumption 1(a) ensure a required Lindeberg condition is satisfied.

Remark 7. Assumption 1(d) expedites tightness of $(X_{nt}(\xi, u))$. If $n^{\alpha(\xi)} = [n^{\xi}]$ the assumption is trivial since $\kappa(\xi, \delta) = (1 + \delta/\eta(\xi)) < \infty \forall \xi \geq 1 - 0$.

Remark 8. Suppose $\eta(\xi, u) := \lim_{n \to \infty} \|X_{nt}(\xi, u)\|_2$ exists for all $\xi$ and $u$, where $\eta(\xi, \cdot)$ is a non-decreasing function on $[0, 1]$. $\eta(0, \cdot) = 0$, $\eta(1, \cdot) = 1$. For fixed $u \in [0, 1]^{k-1}$ if $n^{\alpha(\xi)} = \xi$ then $X(\xi, \cdot)$ is Brownian motion, otherwise $X(\xi, \cdot)$ is transformed Brownian motion.

Remark 9. If $X_{nt}(u) = X_{nt}$ satisfies Assumption 1 and $\lim_{n \to \infty} \|X_{nt}(\xi)\|_2 = \eta(\xi) \in [0, 1]$, then $\sum_{i=1}^n X_{nt} \Rightarrow X(\xi)$ a (transformed) Brownian motion law. This is essentially a version of Davidson and de Jong’s (2000, Theorem 3.1) invariance principle for $L_2$-NED arrays, and matches the generality of Wu and Min’s (2005) results. Our $L_r$-functional array assumption $sup_{r > 0} \|X_{nt}\|_r = O(n^{-\alpha(\xi)})$ is simply a restricted version of Davidson and de Jong’s $L_r$-boundedness condition. Theorem 2.1 goes much farther than either set of results, however, by including cadlag functionals $X_{nt}(u)$ and degenerate tail arrays, the subject of the next section.

A non-functional central limit theorem is merely a special case of Theorem 2.1. In this case, however, Assumption 1(c)–(d) is superfluous. Let $k = 1$ such that $(X_{nt})$ be the $L_r$-functional array associated with $X_t$.

Corollary 2.2. Under Assumption 1(a)–(b) $\sum_{t=1}^n X_{nt} \Rightarrow X$, a Gaussian law with zero mean and finite variance.

3. Invariance principles for tail arrays

Assume $X_t$ has for each $t$ a marginal distribution $P(X_t \leq x)$ with support on $[0, \infty)$ and a regularly varying tail

$$
\tilde{F}_t(x) := P(X_t > x) = x^{-\alpha} L(x), \quad \alpha > 0 \text{ where } L(x) \text{ is slowly varying.}
$$

(11)

See, e.g., Bingham et al. (1987) and Resnick (1987) assume $\tilde{F}_t(x) \tilde{F}_t(x) \to 1$ as $x \to \infty$. Then there exist sequences $\{k_n\}$ and $\{b_n\}$, $1 \leq k_n < n$, $b_n \in \mathbb{N}$, $k_n = o(n)$, $k_n \to \infty$ and $b_n \to \infty$ satisfying (Leadbetter et al., 1983: Theorem 1.7.13)

$$
\lim_{n \to \infty} \frac{n}{k_n} P(X_t > b_n) = 1.
$$

(12)
For any $c = [c_1, c_2]' \in \mathbb{R}^2$ construct a linear combination of the tail arrays $(U_{n,t}, U_{n,t}^*(u))$

\[ Y_{n,t}(c, u) = c_1 U_{n,t} + c_2 U_{n,t}^*(u). \]

Note $E[Y_{n,t}(c, u)] = 0$ by construction, and tail exceedances and events are inherently $L_p$-functional arrays.

**Lemma 3.1.** The array $(Y_{n,t}(c, u))$ satisfies $\sup_{u \in [0,1]} \|Y_{n,t}(c, u)\|_p = O((k_n/n)^{1/p}k_n^{-1/2}) = O(n^{-a(1)})$ for all $r > 0$, where $a(1) > 1/2$, $a(2) = 1/2$ and $2a(2r) > a(r)$. Further $a(r) > 1/r$ for all $r > 2$.

**Remark 10.** Assumption 1(a) is therefore satisfied for $(U_{n,t}, U_{n,t}^*(u))$.

The $L_p$-F-NED properties are particularly insightful for characterizing extremal dependence in $(X_t)$ if $X_{n,t}(u) = U_{n,t}^*(u)$. Properties (9)–(10) reduce to the following functional-extremal-NED property.

**Definition (L$^p$-FE-NED).** $(X_t)$ is $L_q$ FE-NED, $q > 0$, on $(F_{n,t})$ defined in (7), with size $\lambda > 0$ if for any $u \in [0,1]$ and $0 \leq u_1 \leq u_2 \leq 1$, and some $\{l_n\}$, $l_n \to \infty$,

\[
 k_n^{-1/2} \|I_{X_t > b/u} - P(X_t > b/u)[F_{n,t}^{1/l_n}]\|_q \leq d_{n,t}(u) \times \varphi_{l_n} \tag{13}
\]

and

\[
 k_n^{-1/2} \|I_{n,t}(u_1, u_2) - E[I_{n,t}(u_1, u_2)[F_{n,t}^{1/l_n}]]\|_q \leq \left( \frac{d_{n,t}}{\max_{1 \leq i \leq k-1} |u_{2,i} - u_{1,i}|^{1/q}} \times \varphi_{l_n} \right) \tag{14}
\]

where $l_{n,t}(u_1, u_2) := \{b/u < X_t < b/u_1\}$, and $d_{n,t}(u)$ is Lebesgue measurable. The arrays $(d_{n,t}(u), \varphi_{l_n})$ satisfy $\sup_{u \in [0,1]} d_{n,t}(u) = O(k_n^{-1/2}(k_n/n)^{1/4})$ and $\sup_{1 \leq i \leq k-1} \varphi_{l_n} = O(k_n^{-1/2}(k_n/n)^{1/4})$ for some $r \geq q$, and $\varphi_{l_n} = o((k_n/n)^{1/4-1/l_n^2})$.

**Remark 11.** The FE-NED property (13) is NED applied to the tail event $I_{X_t > b/u}$, so it only characterizes memory and heterogeneity in extremes and says nothing about non-extremes $X_t \leq b/u \to \infty$.

**Remark 12.** Any $L^p$-NE process $(X_t)$ with tail (11) is $L^q$-FE-NED for any $q \geq 2$ (see Lemmas A.8 and A.9 in Appendix A.1), thus properties (13)–(14) characterize mixing and geometrically ergodic processes, and at least linear and nonlinear distributed lags, covariance stationary linear and nonlinear GARCH, and stochastic volatility. But FE-NED also covers GARCH data with unit or explosive roots (Hill, 2008b).

**Remark 13.** Since $d_{n,t}(u) \times \varphi_{l_n} = o(k_n^{-1/2}(k_n/n)^{1/4}l_n^{-2})$, $L_2$-FE-NED implies

\[
 \frac{n}{k_n} E[I_{X_t > b/u} - P(X_t > b/u)[F_{n,t}^{1/l_n}]]^2 = O(l_n^{-2}).
\]

Now expand the quadratic, and exploit properties of regularly varying functions and $(n/k_n)P(X_t > b/u) \sim 1$ to deduce $(X_t)$ is $L_2$-FE-NED on $(F_{n,t})$ if and only if

\[
 \frac{n}{k_n} E[P(X_t > b/u)[F_{n,t}^{1/l_n}]]^2 = u^2 + o(l_n^{-2}).
\]

Thus, as $l_n \to \infty$ the extreme event predictor $P(X_t > b/u)[F_{n,t}^{1/l_n}]]$ converges to the event $I_{X_t > b/u}$ in $L_2$-norm, which satisfies $(n/k_n)E[I_{X_t > b/u}] \to u^2$.

**Remark 14.** The analogue to (10)’ is

\[
 k_n^{-1/2} \left[ \sup_{u_{1,i} - u_{2,i} \leq \delta} I_{n,t}(u_1, u_2) - E \left[ \sup_{u_{1,i} - u_{2,i} \leq \delta} I_{n,t}(u_1, u_2)[F_{n,t}^{1/l_n}] \right] \right] \leq K \times d_{n,t} \times \delta^{1/q} \times \varphi_{l_n}, \quad j = 1 \ldots k - 1. \tag{14'}
\]

**Assumption 2.** (a) $X_t$ is $L^q$-FE-NED on $(F_{n,t})$ defined in (7) with size $\lambda = 1/2$, and Lebesgue integrable constants $d_{n,t}(u)$, $f_0^1 u^{-1} d_{n,t}(u) du = O(k_n^{-1/2}(k_n/n)^{1/4})$. The base $(a1)$ is either F-uniform mixing with size $r/2(r - 1)$, $r > 2$, or F-strong mixing base with size $r/(r - 2)$, $r > 2$.

(b) For some bounded function $1 \leq k(\xi, \delta) \leq K$, $\lim_{n \to \infty} [n(\xi + \delta)/n(\xi) - k(\xi, \delta)] \to 0$ exists $\forall \xi \in [\xi - 1 - \delta, \delta] \in [0,1]$. 

If (13) holds for $q = 2$ such that the event process $U_{n,t}^r(u)$ is $L_2$-NED (8), then the exceedance process $(U_{n,t})$ is also $L_2$-NED. Thus (13) characterizes a primitive tail memory property.

**Lemma 3.2.** Under Assumption 2(a) with $q = 2$:

(i) $\{Y_{n,t}(c,u)\}$ is $L_2$-NED on $\{F_{n,t}\}$ coefficients $\varphi_{n,t}$ and $O(k_{n,t}^{1/2}(\ln n)^{1/r})$-constants. In particular $(U_{n,t})$ is $L_2$-NED on $\{F_{n,t}\}$ with coefficients $\varphi_{n,t}$ and constants $x^{-1}k_{n,t}^{1/2}u^{-1}d_{n,t}(u)du$.

(ii) $\{Y_{n,t}(c,u), F_{n,t}\}$ forms a zero mean $L_2$-mixingale array with size $\frac{1}{2}$ and constants $c_{n,t} = O(n^{-1/2})$: there is a sequence $\{\psi_{n,t}\}$ of positive numbers, $\psi_{n,t} = o(t_n^{1/2})$, such that for some $(t_n), t_n \to \infty$ (cf. McLeish, 1975).

Theorem 3.3. Under Assumption 2 with $q = 2$, $\sum_{t=1}^{n(\xi)} Y_{n,t}(c,u) \Rightarrow Y(\xi, c, u)$ on $D_2$, where $Y(\xi, u, c)$ is Gaussian with independent increments, $P(Y(\xi, \cdot) \in \mathbb{C}(\xi, I)) = 1$, and $E\sum_{t=1}^{n(\xi)} Y_{n,t}(c,u)^2 = O(1)$. Further, if (14) holds then $P(Y(\cdot, u) \in \mathbb{C}(0, I^{1/2})) = 1$.

**Remark.** A non-functional version of Corollary 3.3 follows under only the $L_2$-FE-NED property (13), similar to Corollary 2.2. See Hill (2005).

Corollary 3.3 and a Cramér–Wold device for $D_2$-valued processes (e.g. Phillips and Durlauf, 1986) deliver the joint weak limit

$$\sqrt{K_n} \left[ \frac{1}{k_n} \sum_{t=1}^{n(\xi)} \left[ I(\{X_t > b_n/u\} - P(X_t > b_n/u)) \right] \right] \Rightarrow \left[ U^r(\xi, u), U(\xi) \right].$$

The limit processes $(U(\xi))$ and $(U^r(\xi, u))$ are Gaussian with almost surely continuously sample paths along $\xi$, independent increments, and finite variance. Under (14) the sample paths of $U^r(\xi, u)$ are almost surely continuous along $u$.

4. FE-NED arrays and extant FCLT’s

We now discuss extant central limit theorems that cannot include the tail arrays $(U_{n,t}, U_{n,t}^r(u))$. Davidson and de Jong (2000, Theorem 3.1) show $\sum_{t=1}^{n(\xi)} X_t \Rightarrow X(\xi)$ for some sequence of increasing, right-continuous functions $(K_n(\xi))$, where $(X_{n,t})$ is $L_2$-NED (8) on some $\{F_{n,t}\}$ with size $\lambda = \frac{1}{2}$ and constants $d_{n,t}$. They require some positive non-stochastic array $\{c_{n,t}\}$ a sequence $\{g_n\}$, $g_n \to \infty$, $g_n = o(n)$, and $M_{n,t} := \max_{i=1}^{r_n} g_{n+1}^{1/2} + \cdots + g_n^{1/2}$ such that $|X_{n,t}^2/c_{n,t}^2|$ is $L_2$-bounded, $r > 2$, and

$$\max_{1 \leq i \leq r_n+1} M_{n,t} = o(g_n^{-1/2}), \quad \sum_{i=1}^{r_n} M_{n,i}^2 = O(g_n^{-1}), \quad g_n = o(K_n(\xi)), \quad \text{where} \quad r_n(\xi) = \left\lfloor \frac{K_n(\xi)}{g_n} \right\rfloor.$$  

Their framework is quite ingenious for non-degenerate arrays and allows substantial memory and heterogeneity, but cannot be satisfied for tail arrays.

**Lemma 4.1 (Hill, 2007a).** Let $K_n(\xi)/n \to a(\xi) > 0$ a finite constant function. There does not exist an array $(c_{n,t})$ that satisfies $M_{n,t} = o(g_n^{1/2})$ and $\sum_{t=1}^{n(\xi)} M_{n,t}^2 = O(g_n^{-1})$ such that $(U_{n,t}/c_{n,t})$ or $(U_{n,t}^r(u)/c_{n,t})$ are $L_r$-bounded for all $t$ and any $r > 2$.

**Remark.** The imposed properties on $c_{n,t}$ are too restrictive simply because $U_{n,t}$ and $U_{n,t}^r(u)$ are asymptotically degenerate.

Wu and Min (2005, Theorems 1 and 3) establish invariance principles $\sum_{t=1}^{n(\xi)} X_t/\sum_{t=1}^{n(\xi)} X_t \Rightarrow X(\xi)$, for stationary distributed lags $X_t = \sum_{i=0}^{\infty} \psi_i a_{i-t}$, where $a_t = (a_t, a_{t-1}, \ldots, a_1)$ a Borel measurable function of zero mean iid shocks $\{\varepsilon_i\}, \mathbb{E}[\varepsilon_i^2] < \infty$. Under their Theorem 1, for example, coefficient summability conditions are enforced and $a_t$ is $L_p$-weakly dependent of order 1, $p > 2$ (Wu and Min, Eq. (4)). They conclude $|\sum_{t=1}^{n(\xi)} X_t|/\sqrt{n}$ is slowly varying, a property that expedites their invariance principle (see below their Eq. (18)). Their Theorem 2 tackles $\psi_i = (\psi_i)_{n(\xi)}, \frac{1}{2} < \beta < 1$, for slowly varying $\psi_i$.

The simplest case is their Theorem 1 for iid $X_t (\psi_i = 0 \forall i \geq 1, a_t = \varepsilon_t)$ in which the summability conditions automatically hold. Define $S_k := \sum_{t=1}^{k} [I(\{X_t > b_n/e^n\}) - P(X_t > b_n/e^n)]$ and $\sigma_n^2 := \mathbb{E}[S_k^2]$. 

References:

[End of Document]
Lemma 4.2 (Hill, 2007a). If \( X_t \) is iid with distribution tail \((11)\) then \( \sigma^2_0 \to \infty, \|E(S_n|X_0)\|_2 = 0, \) and \( \sigma^2_{n}/n \) is regularly varying with index 1. Further, \( \sigma^2_0/k_n \) is slowly varying.

Remark. Thus \( l(n) := \sigma^2_0/n \) is not slowly varying \( l(\infty)/l(n) \to 1 \forall \theta > 0, \) but regularly varying \( l(\infty)/l(n) \to \lambda^{-1} \) simply because \( P(X_t > b_n e^n) \sim e^{-n(k_n/n)} \) under \((11)\) is degenerate. Wu and Min’s use of slowly varying \( \sigma^2_0/n \) is supported by arguments in Wu and Woodroofe (2004, Lemma 1 and Theorem 1). But the keyLemma 1 of Wu and Woodroofe (2004) is wrong as stated, at least for tail arrays: \( \sigma^2_{n0} \to \infty \) and \( E(S_n|X_0)\|_2 = 0(\sigma^2_{n0}) \) are trivial, but clearly \( \sigma^2_0/n \) is not slowly varying. The correct scale, however, is \( 1/k_n \) as shown in Corollary 3.3.

5. Applications

Assume \( X_t \geq 0 \) a.s. has tail \((11)\). In this section we develop a limit theory for the intermediate tail quantile function \( q_{kn}(\cdot) \), the Hill-estimator \( \hat{q}_{kn}(\cdot) \) in \((5)\), and the tail dependence estimator \( \hat{\rho}_{n}(\cdot, \cdot) \) in \((6)\). Let \( n(\cdot) = \lfloor n(\cdot) \rfloor \) for brevity.

5.1. Tail index estimation and the tail quantile process

We must restrict the regularly varying class \((11)\) in order to expedite asymptotic normality in the manner of Goldie and Smith (1987, SR1). See, also, Hsing (1991) and Hill (2005).

Assumption 3. For some positive measurable function \( g : \mathbb{R} \to \mathbb{R}^+ \)

\[
U(\lambda x)/U(x) - 1 = O(g(x)) \quad \text{ as } x \to \infty.
\]

\( g \) has bounded increase: there exists \( 0 < D, z_0 < \infty \) and \( \tau \leq 0 \) such that \( g(\lambda z)/g(z) \leq D\lambda^\tau \) some for \( \lambda \geq 1, \) \( z \geq z_0. \) \( (k_n) \) and \( g(\cdot) \) satisfy

\[
\sqrt{k_n}g(b_n) \to 0.
\]

Remark. Tails satisfying \((11), (15) \) and \((16)\) include \( F(x) = cx^{-y(1 + O(\ln x)^{-\delta}))} \) and \( F(x) = cx^{-y(1 + O(x^{-\delta}))}. \) The latter characterize GARCH processes \( (Basrak et al., 2002) \) and \((16)\) holds in this case if \( k_n \sim n^\delta, \) \( \delta < 2\theta/(2\theta + \alpha) \) \( (Haeusler and Teugels, 1985). \)

Define

\[
v^2_{1,n}(\cdot) := E\left( k_{n,1/2}^2 \left( \hat{q}_{kn}(\cdot) - \alpha^{-1} \right) \right) \quad \text{ and } \quad v^2_{2,n}(\cdot) := E\left( \sum_{i=1}^{[kn]} U_{1,i} \left( U_{1,i} \right) \right) \).
\]

Theorem 5.1. Under Assumption 2(a) with \( q = 2 \) and Assumption 3 there exist Brownian motion laws \( W_1(\cdot) \) and \( W_2(\cdot) \) with variances

\[
\lim_{n \to \infty} v^2_{1,n}(\cdot) \to \infty, \quad i = 1, 2, \quad \text{such that}
\]

\[
k_{n,1/2}^2 \left( \hat{q}_{kn}(\cdot) - \alpha^{-1} \right) \to W_1(\cdot) \quad \text{ and } \quad k_{n,1/2}^2 \left[ \ln X_{[k_n]}|b_n \right] \to W_2(\cdot).
\]

Remark. Evidently the above result exists under the weakest conditions available in the literature since it covers mixing, geometrically ergodic, Lp-NED and L2-TE-NED data. Non-functional theory exists for iid and strong mixing processes \( (Hall, 1982; Hall and Welsh, 1985; Hsing, 1991; Drees et al., 2004), \) and for data with NED extreme events \( (Hill, 2005). \) See Hill (2005) for a complete literature review and consistent kernel variance estimator of \( v^2_{1,1}(\cdot). \)

5.2. Tail dependence

Now consider a bivariate process \( (X_{1,t}, X_{2,t}) \), where each \( X_{1,t} \) has tail \((11)\) with index \( \alpha \geq 0. \) We want to estimate the joint/marginal tail probability discrepancy:

\[
\hat{\rho}_{n}(i, u) := \frac{n}{k_n} \left[ P_{n,i,h}(u_1, u_2) - P_{1,ni}(u_1)P_{2,ni}(u_2) \right],
\]

where \( P_{n,i,h}(u_1, u_2) := P(X_{1,t} > b_1n/u_1, X_{2,t} > b_2n/u_2) \) and \( P_{1,ni}(u_1) := P(X_{1,t} > b_1n/u_1). \) See Hill (2007b) for comparisons of \( \hat{\rho}_{n}(i, u) \) with tail index and copula based notions of tail dependence. The estimator \( \hat{\rho}_{n}(i, u) \) is defined in \((6)\). For arbitrary \( \lambda \in \mathbb{R}^d, \) \( h \geq 1, \) \( \lambda', \lambda = 1, \) write

\[
Z_{n,i}(\lambda', u, h) := \sqrt{k_n} \left[ \sum_{i=1}^{h} \lambda_{i} \times U^*_{1,n,h-1}(u_1) \times U^*_{2,n,h}(u_2) \right]
\]

so that \( \sum_{i=1}^{[n]} Z_{n,i}(\lambda, u, h) = \sqrt{k_n} \sum_{i=1}^{h} \lambda_{i}\hat{\rho}_{i}(\cdot, \cdot) \).
Lemma 5.2 (Hill, 2007a). For all \( r \geq 1 \) and finite \( h \geq 1 \), \( \|Z_{n,t}(\lambda, u, h)\|_r = O(k^{-1/2}(k_n h)^{1/r}) = O(n^{-a(r)}) \), \( a(1) > \frac{1}{2} \), and \( 2a(2r) > a(r) \). Further, \( a(r) > 1/r \) for all \( r > 2 \).

Lemma 5.3 (Hill, 2007a). Let \( \{X_{t,1}, X_{t,2}\} \) satisfy Assumption 2(a) with \( q = 4 \). Then \( \{Z_{n,t}(\lambda, u, h)\} \) is \( L_2\)-NED on \( \mathcal{F}_{n,t} \) with constants \( d_{n,q}(\lambda, u) \), \( \sup_{n=1}^\infty \|Z_{n,t}(\lambda, u)\|_r = O(k^{-1/2}(k_n h)^{1/r}) \) and coefficients \( \varphi_{n} = O((k_n h)^{1/2 - 1/r} t^{-1/2}) \). Moreover, \( E[Z_{n,t}(\lambda, u, h)] = O(1) \).

By Lemmas 5.2 and 5.3 the conditions of Corollary 3.3 hold for \( \{Z_{n,t}(\lambda, u, h)\} \). A Cramér–Wold device therefore suffices to prove the following claim. Write \( \hat{\rho}^{(h)}_{n}[t,u] := \{\hat{\rho}^{(h)}_{n}[1,u], \ldots, \hat{\rho}^{(h)}_{n}[t,u]\}' \) and \( \rho^{(h)}_{n}[t,u] := \{\rho^{(h)}_{n}[1,u], \ldots, \rho^{(h)}_{n}[t,u]\}' \).

Theorem 5.4. If \( \{X_{t,1}, X_{t,2}\} \) satisfy Assumption 2(a) with \( q = 4 \) then

\[
\sqrt{k_n}[\hat{\rho}^{(h)}_{n}[t,u] - \rho^{(h)}_{n}[t,u]] \Rightarrow W(\zeta, u)
\]

is a Gaussian element of the h-vector space \( D_h \) with almost surely continuous sample paths along \( \zeta \), independent increments, and \( \|W(\zeta, u)\|_2 < \infty \). If each \( \{X_{t,i}\} \) satisfies (14) then \( P(W(\zeta, u) \in \mathcal{C}[0, 1]'' \) = 1.

Remark 15. Notice that although the bivariate joint tail \( P_{n,0}h(u_1, u_2) \) is being estimated, we do not require a model nor any assumptions concerning the joint tail. Further, we do not require any restrictions on non-extremes. Compare this with the marginal iid and joint tail shape restrictions typically enforced in the literature (e.g., Ledford and Tawn, 1997; Schmidt and Stadtmüller, 2006; Kluppelberg et al., 2007).

Remark 16. In order for \( \hat{\rho}^{(h)}_{n}[t,u] \) to be usable in practice, either arbitrary choices of the threshold sequences \( \{b_{n,i}\} \) are required, or a consistent plug-in, e.g., \( X_{min}(k_{n+1}) \). See Hill (2007b, Lemma A.2) for a proof that use of \( X_{min}(k_{n+1}) \) does not affect the non-functional distribution limit of \( \hat{\rho}^{(h)}_{n}[t,u] \) under Assumption 2(a). It is straightforward to show the result directly carries over to the functional limit case.

Acknowledgment

I would like to thank an anonymous referee for helpful comments.

Appendix A.

A.1. Proofs of main results

The proofs require the following notation. Define sequences \( g_n \), \( l_n \) and \( r_n(\cdot) \) as follows: \( 1 \leq g_n \to \infty \) and

\[
\begin{align*}
1 & \leq g_n = o(n(\zeta)), \\
1 & \leq l_n \leq n - 1 - n(\zeta) - 1, \\
l_n/g_n & \to 0, \quad l_n \to \infty, \\
r_n(\delta) = [n(\min(\delta, 1))/g_n] \quad \text{for} \quad \delta > 0,
\end{align*}
\]

and assume

\[
g_n = O\left(n^{\min[2a(4)+a(2)-1/2,2a(2r)-a(r)]}\right).
\]

The latter is always possible as long as \( \min(2a(4)+a(2)-1/2,2a(2r)-a(r)) > 0 \), cf. Assumption 1(a), since \( 2a(4)+a(2) > 1 \) is implied by \( a(2) = \frac{1}{2} \) and \( 2a(2r) > a(r) \). For the array of \( \sigma \)-fields \( \{\mathcal{F}_{n,t}\} \) defined by (7) construct the sub-field

\[
\hat{\mathcal{F}}_{n,t} := \sigma\left(\bigcup_{t < g_n} \mathcal{F}_{n,t} \right) : i = 1 \ldots r_n(\zeta).
\]

Now define blocks

\[
Z_{n,i}(u) := \sum_{t = (i-1)g_n + 1}^{i g_n} X_{n,t}(u).
\]
For any point \((\xi, \eta)\) or sequence of points \(\{(\xi_j, u_j)\}_{j=1}^h\), and \(\pi \in \mathbb{R}^h\), \(\pi' = 1\), define

\[
W_{n,j}(u) := E[Z_{n,j}(u)|\hat{F}_{n,j}] - E[Z_{n,j}(u)|\hat{F}_{n,j-1}],
\]

\[
W_n(\xi, \eta) := \sum_{i=1}^{r_n(\xi)} W_{n,j}(u),
\]

\[
\hat{W}_{n,j}(u, \pi) := \sum_{i=1}^{h} \pi_j W_{n,j}(u), \quad i = r_n(\xi_{i-1}) + 1, \ldots, r_n(\xi), \ l = 1 \ldots h.
\]

(20)

Notice \(\{W_{n,j}(u), \hat{F}_{n,j}\}\) forms a martingale difference array. The main result, Theorem 2.1, is proven by verifying the conditions of Lemma A.1 which shows \(\{X_n(\xi, \eta) = W_n(\xi, \eta) + \psi_t(1)\}\) and delivers a central limit theorem for \(W_n(\xi, \eta)\). This approach was exploited in Davidson (1992), de Jong (1997) and Davidson and de Jong (2000) for non-degenerate, and therefore non-tail \(L_2\)-NED arrays.

**Proof of Theorem 2.1.** Step 1 (weak convergence): Under Assumption 1(b), Lemma A.4(i) in Appendix A.2 shows \(\{X_n(\xi, \eta), \ F_{n,t}\}\) forms an \(L_2\)-mixingale array with size \(1\) and coefficients \(c_{n,t}\) then \(E(\sum_{n=t\ldots1} y_{n,t})^2 = O(\sum_{n=t\ldots1} c_{n,t}^2)\).

Analogous to de Jong’s (1997, A.7–A.12) argument, because \(\{X_{n,t}(\eta), \ F_{n,t}\}\) forms an \(L_2\)-mixingale array with size \(\lambda = \frac{1}{2}\), for \(t \in A_{n,t}\) the array \(E[\{X_n(\xi, \eta) = W_n(\xi, \eta) + \psi_t(1)\}]\) is an \(L_2\)-mixingale with constants \(c_{n,t}(\eta)\psi_t(\eta)\) and coefficients \(\psi_t^{1-\eta} = o(1_{\eta}(\eta))\) for some sufficiently tiny \(\eta > 0\). McLeish’s (1975) bound now gives

\[
E\left(\sum_{i=1}^{r_n(\xi)} E[Z_{n,j}(u)|\hat{F}_{n,j-1}] \right)^2 \leq O\left(\sum_{i=1}^{r_n(\xi)} \sum_{t=1}^{\frac{r_n(\xi)}{\eta}} \sum_{l=1}^{\frac{r_n(\xi)}{\eta}} c_{n,t}(u)\psi_t^{2\eta}\right) = O(r_n(\xi)\eta n^{-1}I_n^{\eta}) = o(1)\).

Condition (c): The proof mimics (b).

Condition (d): Compactly write for any finite sequence of points \(\{(\xi_j, u_j)\}_{j=1}^h\)

\[
Z_{n,j}(j) = Z_{n,j}(u_j) \quad \text{and} \quad W_{n,j}(j) = W_{n,j}(u_j),
\]

and note from (20) we can always write

\[
\sum_{i=1}^{r_n(\xi)} W_{n,j}^2(u, \pi) = \sum_{i=1}^{h} \sum_{i=r_n(\xi_{i-1}) + 1}^{h} \left(\sum_{j=1}^{h} \pi_j W_{n,j}(j)\right)^2.
\]

*By Theorem 1.6 of McLeish (1975), if \(\{y_{n,t}, F_{n,t}\}\) forms an \(L_2\)-mixingale array with size \(\frac{1}{2}\) and coefficients \(c_{n,t}\) then \(E[\sum_{n=1}^{\infty} y_{n,t}^2] = O(\sum_{n=1}^{\infty} c_{n,t}^2)\).*
Analogous to arguments in de Jong (1997, A.13–A.17), it follows

\[
\sup_{\pi, \pi'} \left\| \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \left( \sum_{j=l}^{h} \pi_{j} Z_{n, i}(j) \right)^{2} - \sum_{i=1}^{h} W_{n, i}^{2}(u, \pi) \right\|_{1}
\]

\[
= \sup_{\pi, \pi'} \left\| \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \left( \sum_{j=l}^{h} \pi_{j} Z_{n, i}(j) \right)^{2} - \left( \sum_{j=l}^{h} \pi_{j} W_{n, i}(j) \right)^{2} \right\|_{1}
\]

\[
\leq K \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2}
\]

\[
= O \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \right)
\]

Now use Assumption 1(a, b) and Lemma A.4(iii) to deduce \( \sup_{\pi, \pi'} \left\| \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \sum_{t \in A_{t}(l)} c_{n, t}^{2} W_{n, t}^{2n} \right\|_{1}^{1/2} \times \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} c_{n, t}^{2} \right)^{1/2}
\]

\[
= O \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \right)
\]

Condition (e): For any \( \xi, \delta \in [0, 1] \) and \( u \in [0, 1]^{k-1} \), and some integer sequence \( \{ r_{n}^{u}(\xi) \} \) satisfying

\[
0 \leq \left[ \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \right) = O(l_{n}^{-\eta/2}) = o(1).
\]

use Minkowski's inequality to deduce

\[
\left\| \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \right\|_{2}^{1/2} \times \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} c_{n, t}^{2} \right)^{1/2}
\]

Under the maintained assumptions \( \{ X_{n, i}(u), F_{n, t} \} \) forms an \( L_{2} \)-mixingale array with size \( \lambda = \frac{1}{2} \) and constants \( \kappa_{n, t}(u) = O(n^{-1/2}) \). Similarly, for each \( t \in A_{t}(u) \), \( \| X_{n, i}(u) - E[X_{n, i}(u)|F_{n, t-1}] \| \leq \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} c_{n, t}^{2} \right)^{1/2} \times \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \right)
\]

\[
= \delta \times O(l_{n}^{-\eta/2}) = o(1)
\]

Now, by Assumption 1(d) and the construction of \( r_{n}^{u}(\xi) \) there exists a finite mapping \( \kappa(\xi, \delta) \equiv 1 \) satisfying

\[
\frac{\delta r_{n}^{u}(\xi)}{n} \leq \frac{\delta r_{n}^{u}(\xi)}{n} \leq \left( \frac{r_{n}^{u}(\xi) + \delta}{r_{n}^{u}(\xi)} - 1 \right) \times (1 + o(1)) \rightarrow \kappa(\xi, \delta) - 1 < \infty.
\]

But if \( \delta r_{n}^{u}(\xi) \) is bounded then so is \( r_{n}^{u}(\xi) \) since \( \delta \in [0, 1] \). The proof is complete by exploiting the martingale difference property of \( \{ W_{n, i}(u), F_{n, t} \} \):

\[
\sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} \| Z_{n, i}(j_1) - W_{n, i}(j_1) \|_{2} \times \| Z_{n, i}(j_2) \|_{2} \times \left( \sum_{i=1}^{h} \sum_{l=i}^{r_{i}^{(\xi)}} c_{n, t}^{2} \right)^{1/2}
\]

\[
\leq \delta \times \kappa \quad \text{for large } n \text{ and some } \kappa \geq 1.
\]
Condition (f): For any \( u \in [0, 1]^{k-1} \) and \( u_1, u_2 \in [0, 1], j = 1 \ldots k - 1 \), write

\[
\Delta X_{nt}(u_1, u_2) := X_{nt}(\{u_1 \neq j, u_2\}) - X_{nt}(\{u_1 \neq j, u_2\})
\]

The F-NED property (10) and Lemma A.4(ii) imply \( \{\Delta X_{nt}(u_1, u_2), F_{nt}\} \) forms an \( L_2 \)-mixing array with size \( \frac{1}{n} \) and constants \( \tilde{c}_{nt} \times \max_{1 \leq i \leq k-1} |u_2 - u_1|/|u_2 - u_1|^{1/2}, \sup_{\phi \geq 1} \tilde{c}_{nt} = O(n^{-1/2}). \) Now mimic (21) and the subsequent argument to obtain

\[
\|W_n(\cdot, u_1) - W_n(\cdot, u_2)\|_2 \leq \left\| \sum_{t=1}^{\tau_n^{(z)}} \left( \Delta X_{nt}(u_1, u_2) - E[\Delta X_{nt}(u_1, u_2)|\tilde{F}_{nt}] \right) \right\|_2 \\
+ \left\| \sum_{t=1}^{\tau_n^{(z)}} E[\Delta X_{nt}(u_1, u_2)|\tilde{F}_{nt-1}] \right\|_2 \\
= O\left( \sum_{t=1}^{\tau_n^{(z)}} \sum_{1 \leq a \leq k} W_n(\cdot, u_1) \right)^{1/2} \times |u_2 - u_1|^{1/2} \\
= |u_2 - u_1|^{1/2} \times O(\tau_n^{(z)} g_{nt}/n)^{1/2} \leq K \times |u_2 - u_1|^{1/2}.
\]

Since the right-hand side is not a function of \( \xi \) the inequality is uniform in \( \xi \in [\xi, 1] \).

Condition (g): Use \( \Delta X_{nt}(u_1, u_2, u_2) \) from above and define

\[
Z_{nt, j}(\delta) := \sup_{u_1, j \leq u_2 \leq u_1 + \delta} |\Delta X_{nt}(u_1, u_2, u_2)|, \\
W_{nt, j}(\delta) := E[Z_{nt, j}(\delta)|\tilde{F}_{nt}] - E[Z_{nt, j}(\delta)|\tilde{F}_{nt-1}].
\]

Property (10) implies \( \{Z_{nt, j}(\delta), F_{nt}\} \) is \( L_2 \)-NED on \( F_{nt} \) with constants \( k_0^{1/2} d_{nt}, \sup_{\phi \geq 1} \tilde{c}_{nt} = O(n^{-\theta(2)}), \) and coefficients \( \phi_{nt} = O(n^{(\theta(2)-\theta(1))}/n^2) \), where \( \theta(2) = 1/2 \) under Assumption 1(a). An argument identical to the proof of Lemma A.4(ii) reveals \( \{Z_{nt, j}(\delta), F_{nt}\} \) forms an \( L_2 \)-mixing array with size \( \frac{1}{n} \) and constants \( \tilde{c}_{nt} = \delta^{1/2} \times O(n^{-1/2}) \). It is similarly easy to show \( \{W_{nt, j}(\delta), F_{nt}\} \) forms an \( L_2 \)-mixing array with size \( \frac{1}{n} \) and constants \( \tilde{c}_{nt} = \delta^{1/2} \times O(n^{-1/2}) \) (cf. de Jong, 1997). McLeish’s (1975) bound again delivers

\[
E\left( \sup_{u_1 \leq u_2 \leq u_1 + \delta} |W_n(\cdot, u_1) - W_n(\cdot, u_2)| \right)^2 \leq E\left( \sum_{t=1}^{\tau_n^{(z)}} \sum_{1 \leq a \leq k} W_n(\cdot, u_1) \right)^2 \\
= O\left( \sum_{t=1}^{\tau_n^{(z)}} \tilde{e}_{nt}^2 \right) \leq K\delta.
\]

Step 2 (increments): For any \( 0 < \tilde{c}_k < \xi < 1 \) and \( u_k, u_k \in [0, 1]^{k-1} \) we need to show

\[
E[|X_n(\tilde{c}_k, u_k) - X_n(\tilde{c}_k, 1, u_k)|] \times E[|X_n(\xi, u_k) - X_n(\xi, 1, u_k)|] = o_p(1).
\]

First, decompose the increment \( X_n(\tilde{c}_k, u_k) - X_n(\tilde{c}_k, 1, u_k, 1): \)

\[
X_n(\tilde{c}_k, u_k) - X_n(\tilde{c}_k, 1, u_k) = [X_n(\tilde{c}_k, u_k) - X_n(\tilde{c}_k, 1, u_k)] + [X_n(\tilde{c}_k, 1, u_k) - X_n(\tilde{c}_k, 1, u_k)]
\]

Analogous to arguments in Davidson and de Jong (2000, pp. 635–636 and Lemma A.3), use McLeish’s (1975) bound, the properties \( \sup_{u \in [0, 1]^{k-1}} c_{nt}(u) = O(n^{-1/2}), n(\xi) = n(\xi) \rightarrow \infty, l > k, \) and \( n(1) \leq n \) to deduce for arbitrary \( \delta \in [0, 1] \)

\[
E[A_n, A_n] \leq \sum_{t=1}^{n(\xi)} \sum_{l=t}^{n(\xi+\delta)} X_n(u_l) \times \sum_{t=1}^{n(\xi+\delta)} X_n(u_l) + \sum_{t=1}^{n(\xi+\delta)} E[X_n(u_l)X_n(u_l)] \times l(\xi - t) \geq n(\tilde{c}_k, 1, u_k) = o_p(1).
\]
Similarly, since under Lemma A.4(ii) \( \{ X_n \ell(t, u) \} \) is an \( L_2 \)-mixing array with size \( \frac{1}{2} \) and constants proportional to \( \xi_{n,t} \), sup \( t \geq 1 \) \( \xi_{n,t} = O(n^{-1/2}) \), for arbitrary \( \delta > 0 \)

\[
\left| E \left[ A_{n,k} B_{n} \right] \right| \leq \frac{\sum_{t=1}^{n} X_{n}(u_{k})}{n^{\frac{1}{4}}} \left( \sum_{t=1}^{n} (X_{n}(u_{t}) - X_{n}(u_{t-1})) \right)
\]

\[
+ \frac{\sum_{t=n(\xi_{k-1}+2\delta)+1}^{n} X_{n}(u_{k})}{n^{\frac{1}{2}}} \left( \sum_{t=n(\xi_{k-1}+\delta)+1}^{n} (X_{n}(u_{t}) - X_{n}(u_{t-1})) \right)
\]

\[
+ \sum_{s,t=1}^{n} E \left[ |X_{n,t}(u_{k})| (X_{n,s}(u_{t}) - X_{n,s}(u_{t-1})) \right] \times I \left( (s-t) \geq n(\xi_{k-1}+2\delta) - n(\xi_{k-1}+\delta) \right)
\]

\[
= O \left( \left( \sum_{t=1}^{n} c_{n,t}^{2} \right)^{1/2} \left( \sum_{t=1}^{n} c_{n,t}^{2} \right)^{1/2} \right)
\]

\[
+ O \left( \left( \sum_{t=n(\xi_{k-1}+2\delta)+1}^{n} c_{n,t}^{2} \right)^{1/2} \left( \sum_{t=n(\xi_{k-1}+\delta)+1}^{n} c_{n,t}^{2} \right)^{1/2} \right)
\]

\[
= o_\Omega(1),
\]

because \( c_{n,t}(u) \) and \( \xi_{n,t} \) are uniformly \( O(n^{-1/2}) \), \( 0 < \xi_{k} < \xi_{t} < 1 \) and \( n(1) \leq n \).

Finally, \( 0 < \xi_{k} < \xi_{t} < 1, n(\xi_{k}) < n(\xi_{t}) \leq n \) and the \( L_2 \)-mixingale property of \( X_{n,t}(u_{t}) - X_{n,t}(u_{t-1}) \) imply

\[
\left| E \left[ B_{n,k} B_{n} \right] \right| \leq \frac{\sum_{t=1}^{n} (X_{n}(u_{k}) - X_{n}(u_{k-1}))}{n^{\frac{1}{4}}} \left( \sum_{t=1}^{n} (X_{n}(u_{t}) - X_{n}(u_{t-1})) \right)
\]

\[
= O \left( \left( \sum_{t=1}^{n} c_{n,t}^{2} \right)^{1/2} \left( \sum_{t=1}^{n} c_{n,t}^{2} \right)^{1/2} \right)
\]

\[
= O((n(\xi_{k-1})/n)^{1/2} (n(\xi_{t-1})/n)^{1/2}) = o_\Omega(1).
\]

**Proof of Corollary 2.2.** The claim follows from conditions (a)--(d) of Lemma A.1, which are verified in the proof of Theorem 2.1 under Assumption 1(a,b).

**Proof of Lemma 3.1.** By Lemma A.2 in Hill (2005) for any \( r \geq 1 \)

\[
\lim_{n\to\infty} \frac{n}{k_{n}} \frac{1}{k_{n}^{1/2}} \| U_{n,t}(u) \|_{r} \leq K \quad \text{and} \quad \lim_{n\to\infty} \frac{n}{k_{n}} \frac{1}{k_{n}^{1/2}} \| U_{n,t}(u) \|_{r} \leq K.
\]

Since \( k_{n} \to \infty \) as \( n \to \infty \) it follows that \( k_{n}^{(1/2-1/n-1/2)} n^{1/2} = n^{-1} \), \( k_{n}^{(1/2-1/n-1/2)} n^{-1/2} = n^{-1/2} \), and \( k_{n}^{(1/2-1/n-1/2)} n^{-1/2} = n^{-1/2} \). Hence for some \( a(r) \) each \( \| U_{n,t}(u) \|_{r} \leq O(n^{-a(r)}) \), where \( a(1) > 1/2 \) and \( a(2) > 1/2 \). Similarly,

\[
O(n^{-2a(2r)}) = O(k_{n}^{-(1/2-1/2r)} n^{-1/2}) \leq O(k_{n}^{-(1/2-1/2r)} n^{-1/2})
\]

\[
= O(k_{n}^{-(1/2-1/2r)} n^{-1/2}) \leq O(n^{-a(r)}) \times k_{n}^{-1/2} \leq O(n^{-a(r)}),
\]

hence \( 2a(2r) > a(r) \).

**Proof of Lemma 3.2.** The \( L_2 \)-NED and \( L_2 \)-mixingale claims follow from Lemma 3 of Hill (2005) and a change of variable \( e^{-\nu} = u, \nu \geq 0 \). The bound \( E \left( \sum_{t=1}^{n} Y_{n,t}(c, u)^{2} \right) = O(1) \) follows from McLeish (1975).
Proof of Theorem 5.1. The claim for $\hat{Z}_{[\cdot]}^{-1}$ follows from Lemma A.7 and Corollary 3.3:

$$k_n^{1/2} (\hat{Z}_{[\cdot]}^{-1}(\zeta) - \zeta^{-1}) = \sum_{i=1}^{[n^2]} (U_{ni} - \zeta^{-1} U_{n_i} \{u^{[k_n]^{-1/2}}\}) + o_p(1)$$

$$\Rightarrow W(\zeta).$$

Now consider $X_{[\cdot]}$: We infer from Theorem 2.4 of Hsing (1991) that under Assumption 3 for some process $Z(\zeta)$ if $\sum_{i=1}^{[n^2]} U_{ni} \{u^{[k_n]^{-1/2}}\} \Rightarrow Z(\zeta)$ then $k_n^{1/2} \ln X_{[\cdot]}(\zeta)+b_n \Rightarrow Z(\zeta)$. Corollary 3.3 completes the proof: $\sum_{i=1}^{[n^2]} U_{ni} \{u^{[k_n]^{-1/2}}\} \Rightarrow W_2(\zeta)$ for some Gaussian element $W_2(\zeta)$ of $D(\Sigma, 1)$ with variance $\lim_{n \to \infty} \mathbb{E}[W_2(\zeta)]^2 = \lim_{n \to \infty} \mathbb{E} (\sum_{i=1}^{[n^2]} U_{ni} \{u^{[k_n]^{-1/2}}\})^2 < \infty$. \hfill $\square$

A.2. Supporting lemmata

The following results exploit the constructions in (17)–(20). First, Lemma A.1 delivers an omnibus central limit theorem and functional central limit theorem for functional arrays $X_n(u)$.

**Lemma A.1.** Let $\{X_n(u)\}$ be an $L_2$-functional tail array with $rth$-moment index $a(r)$, $2a(4) + a(2) > 1$, and let $\|X_n(\zeta, u)\|_2 = O(1)$. Assume $\{g_n\}$ in (17) satisfies $g_2 = 0(\|X_n(\zeta, u)\|_2 = O(1))$. Consider the following conditions:

(a) $\sum_{i=1}^{\lfloor n^2 \rfloor} X_n(u) \rightarrow^p 0,$

(b) $\sum_{i=1}^{\lfloor n^2 \rfloor} E[Z_n(u)|\mathcal{F}_{ni-1}] \rightarrow^p 0,$

(c) $\sum_{i=1}^{\lfloor n^2 \rfloor} (Z_n(u) - E[Z_n(u)|\mathcal{F}_{ni}]) \rightarrow^p 0,$

(d) $\sup_{n \geq 1} \left\| \sum_{i=1}^{\lfloor n^2 \rfloor} W_n^2(u, \pi) - 1 \right\|_2 \rightarrow^p 0,$

(e) $\sum_{i=1}^{\lfloor n^2 \rfloor} E[W_n(u)]^2 \leq \delta \times \kappa, \quad \forall \delta \in [0, 1]$

for some $\kappa \geq 1$ and some sequence $\{r_n(\zeta)\}$ satisfying $0 \leq [\delta \times r_n(\zeta)] \leq r_n(\zeta) + \delta - r_n(\zeta)$; and for each $j = 1 \ldots k - 1$ and any $u_1, u_2 \in [0, 1]^{k-1}$

(f) $\sup_{\zeta \in [\zeta, 1]} \|W_n(\zeta, u_1) - W_n(\zeta, u_2)\|_2 \leq K|u_{1,j} - u_{2,j}|^{1/2},$

and for each $\zeta \in [\zeta, 1]$

(g) $E \left( \sup_{u_1, u_2 \in [\zeta, 1]} |W_n(\zeta, u_1) - W_n(\zeta, u_2)|^2 \right) \leq K\delta.$

(i) For any points $\zeta \in (0, 1]$ and $u \in [0, 1]^{k-1}$ under (a)–(d) $X_n(\zeta, u) \rightarrow X(\zeta, u)$, a zero mean Gaussian law with finite variance.

(ii) Under (a)–(f) $X_n(\zeta, u)$ is a Gaussian element of $D_k$ with covariance function $E[X(\zeta, u)X(\zeta, u)]$ and $P(X(\zeta, \cdot)) \in C(\zeta, 1)$ = 1.

If additionally (g) holds then $P(X(\zeta, u) \in C(0, 1)^{k-1}) = 1.$

**Remark.** Conditions (a)–(c) imply $X_n(\zeta, u)$ is approximable by martingale differences ($W_n(u)$). Condition (d) ensures convergence of the finite dimensional distributions of ($W_n(u)$), and conditions (e) and (f) ensure the sequence ($W_n(u)$) is uniformly tight with respect to $\zeta$ and $u$, respectively. Thus, (a)–(d) deliver a CLT for tail arrays $X_n(\cdot, \cdot)$, (a)–(e) an FCLT for $X_n(\cdot, \cdot)$, and (a)–(f) an FCLT for $X_n(\cdot, u)$.

**Lemma A.2.** Under conditions (a)–(d) of Lemma A.1, $W_n(\zeta, u) \rightarrow W(\zeta, u)$ with respect to finite dimensional distributions, where $W(\zeta, u)$ is Gaussian with covariance function $E[W(\zeta, u)W(\zeta, u)]$. 

Lemma A.3. Under conditions (a)–(f) of Lemma A.1 the sequence \( \{W_n(\xi, u)\} \) is uniformly tight on \( [\xi, 1] \times [0, 1]^{k-1} \), and \( P(W(\xi, \cdot) \in C[\xi, 1]) = 1 \). Under condition (g) \( P(W(\cdot, u) \in C[0, 1]^{k-1}) = 1 \).

Lemma A.4. (i) Under Assumption 1(a,b) \( \{X_n(t, u), F_{n,t}\} \) forms an \( L_2 \)-mixingale array with coefficients \( \psi_{u_t} = o(\ell_n^{-1/2}) \) and constants \( c_{u_t}(u) \), \( \sup_{n, t} E[|X_n(t, u)|^2] = O(n^{-1/2}) \):

\[
\|E[X_n(t, u)F_{n,t-l}]\|_2 \leq c_{u,t}(u)\psi_{u_t},
\]

\[
\|X_n(t) - E[X_n(t)F_{n,t+l}]\|_2 \leq c_{u,t}(u)\psi_{u_{t+1}}.
\]

(ii) Write \( \Delta X_n(t_1, t_2) := X_n(t_1) - X_n(t_2) \). Under Assumption 1(a,c) \( \{\Delta X_n(t_1, t_2), F_{n,t}\} \) forms an \( L_2 \)-mixingale array with coefficients \( \psi_{u_t} = o(\ell_n^{-1/2}) \) and constants \( c_{u_t} \times \max_{1 \leq i \leq k-1} \|u_{t,j} - u_{t,j+1}\|^{1/2} \), \( \sup_{t \geq 1} c_{u_t} = O(n^{-1/2}) \):

\[
\|E[\Delta X_n(t_1, t_2)F_{n,t-l}]\|_2 \leq \left( c_{u,t} \times \max_{1 \leq i \leq k-1} \|u_{t,j} - u_{t,j+1}\|^{1/2} \right) \psi_{u_t},
\]

\[
\|\Delta X_n(t_1, t_2) - E[\Delta X_n(t_1, t_2)F_{n,t+l}]\|_2 \leq \left( c_{u,t} \times \max_{1 \leq i \leq k-1} \|u_{t,j} - u_{t,j+1}\|^{1/2} \right) \psi_{u_{t+1}}.
\]

(iii) Let \( \{\tilde{z}_i, u_i\}_{i=1}^h \) be arbitrary points on \( [\xi, 1] \times [0, 1]^{k-1} \), \( h \geq 1 \). Under Assumption 1(a,b)

\[
\sup_{n \rightarrow \infty} \left| \sum_{i=1}^{h} \sum_{t \geq 0} \sum_{i=1}^{h} r_n(\tilde{z}_i, u_i) Z_n(u_i) - \left( \sum_{i=1}^{h} \sum_{t \geq 0} \sum_{i=1}^{h} r_n(\tilde{z}_i, u_i) Z_n(u_i) \right) \right| \rightarrow 0, \quad \forall \{\tilde{z}_i, u_i\}_{i=1}^h.
\]

Lemma A.5 (de Jong, 1997, Lemma 4). For any \( L_2 \)-mixingale array \( \{Y_{n,t}, F_{n,t}\} \) with size \( \lambda = \frac{1}{2} \) and constants \( c_{u,t} \), \( \sup_{t \geq 1} c_{u,t} = O(n^{-1/2}) \)

\[
\lim_{n \rightarrow \infty} \left| \sum_{i=1}^{h} \sum_{t \geq 0} \sum_{i=1}^{h} \sum_{i=1}^{h} \sum_{t \geq 0} \sum_{i=1}^{h} E[Y_{n,t}Y_{n,t}] \right| = 0.
\]

Lemma A.6. Under Assumption 1(a,b) \( \sum_{i=1}^{h} (Z_n^i(u) - E[Z_n^i(u)]) \rightarrow 0 \ \forall \tilde{z}, u \in [\xi, 1] \times [0, 1]^{k-1} \).

Lemma A.7 (Hill, 2007a). Under the conditions of Theorem 5.1 for any \( u \in [0, 1] \)

\[
\kappa_n^{1/2} \left( \tilde{z}_{k_n} - \alpha^{-1} \right) = \left( \sum_{i=1}^{n} (U_{n,t} - \alpha^{-1} U_{n,t}(u^{k_n} t^{-1/2})) \right) + o_p(1).
\]

Lemma A.8 (Hill, 2007a). Let \( \{X_t\} \) be \( LP_{-NED} \), \( p \in [0, 2] \), on \( \{F_{n,t}\} \) with constants \( d_t, \sup_{t \geq 1} d_t < \infty \), and coefficients \( \varphi_{u_t} \) of size \( \lambda > 0 \). Then \( \{X_t\} \) satisfies the \( L_q \)-FE-NED property (13) for any \( q \geq 2 \) and some displacement sequence \( f_{n,t} \), \( n \rightarrow \infty \), with constants \( d_{u}(u) \) and coefficients \( \varphi_{u_t} \) of size \( \lambda \times \min(p, 1/(2q)) \). In particular, \( d_{u}(u) \) is Lebesgue measurable, \( \sup_{u \in [0, 1]} d_{n,t}(u) = O((\kappa_{u}(n) n^{-1/2} k_{n}^{-1/2}) \) and \( \int_{a}^{b} u^{-1} d_{u}(u) du = O((\kappa_{u}(n) n^{-1/2} k_{n}^{-1/2}) \) for some \( r \geq q \). Further \( \varphi_{u_t} \in [0, 1] \) uniformly in and \( \varphi_{u_t} = O((\kappa_{u}(n) n^{-1/2} k_{n}^{-1/2}) \).

Lemma A.9 (Hill, 2007a). Let \( \{X_t\} \) be \( LP_{-NED} \) on \( \{F_{n,t}\} \) with constants \( d_t, \sup_{t \geq 1} d_t < \infty \), and coefficients \( \varphi_{u_t} \) of size \( \lambda > 0 \). Then \( \{X_t\} \) satisfies the \( L_q \)-FE-NED property (14) for any \( q \geq 2 \) with constants \( \tilde{d}_{n,t} \), \( \sup_{t \geq 1} \tilde{d}_{n,t} = O((\kappa_{u}(n) n^{-1/2} k_{n}^{-1/2}) \) for some \( r \geq q \) and coefficients \( \varphi_{u_t} \).

Proof of Lemma A.1. It suffices to prove \( X_n(\xi, u) \) convergences in finite dimensional distributions, and \( \{X_n(\xi, u)\} \) is tight on \( [\xi, 1] \times [0, 1]^{k-1} \).
Decompose $X_n(\xi, u)$:

$$X_n(\xi, u) = \sum_{i=1}^{n(\xi)} W_{ni}(u) + \sum_{t=t(\xi)/g_n+1}^{n(\xi)} X_n(u) + \sum_{i=1}^{n(\xi)} \mathbb{E}[Z_n(u)|\tilde{F}_{ni-1}]$$

$$+ \sum_{i=1}^{n(\xi)} (Z_n(u) - \mathbb{E}[Z_n(u)|\tilde{F}_{ni-1}]) + \sum_{i=1}^{r_n(\xi)} \sum_{t=(i-1)g_n+1}^{i-1} X_n(u)$$

$$= \sum_{i=1}^{r_n(\xi)} W_{ni}(u) + \sum_{t=t(\xi)/g_n+1}^{n(\xi)} X_n(u) + R_n(u),$$

say. By the definition of an $L_2$-functional array and $r_n(\xi) = [n(\xi)/g_n]$}

$$\left\| \sum_{t=t(\xi)/g_n+1}^{n(\xi)} X_n(u) \right\|_1 = O((n(\xi) - r_n(\xi)g_n)n^{-a(1)}) = o(1),$$

and conditions (a)–(c) imply $R_n(u) = o_p(1)$, hence

$$X_n(\xi, u) = \sum_{i=1}^{r_n(\xi)} W_{ni}(u) + o_p(1) = W_n(\xi, u) + o_p(1).$$

Lemma A.2 proves the CLT claim (i), and the FCLT claim (ii) follows from Lemmas A.2 and A.3. □

**Proof of Lemma A.2.** Pick any $\pi \in ]1, 1']$, $\pi' = 1$, and notice for any finite collection $\{(\xi_j, u_j)\}_{j=1}^{h}, \xi_1 \leq \cdots \leq \xi_h$, by construction, cf. (20),

$$\sum_{j=1}^{h} \pi_j W_{n}(\xi_j, u_j) = \sum_{i=1}^{r_n(\xi_i)} \tilde{W}_{ni}(u, \pi).$$

By construction $\{\tilde{W}_{ni}(u, \pi), \tilde{F}_{ni}\}$ forms a martingale difference array. We will show under conditions (a)–(d) of Lemma A.1

$$\sum_{i=1}^{r_n(\xi_i)} \tilde{W}_{ni}(u, \pi) \xrightarrow{d} N\left(0, \lim_{n \to \infty} \mathbb{E}\left[\left(\sum_{i=1}^{r_n(\xi_i)} \tilde{W}_{ni}(u, \pi)\right)^2\right]\right)$$

is a consequence of Theorem 2.3 of McLeish (1974), where $\lim_{n \to \infty} \|\sum_{i=1}^{r_n(\xi_i)} \tilde{W}_{ni}(u, \pi)\|_2 \leq K$ follows from (22) and $(X_n(\xi, u))_{12} = O(1)$. A Cramér–Wold device completes the proof.

We need only verify McLeish’s conditions (a)–(c). McLeish’s condition (c) is condition (d) of Lemma A.1. Moreover, McLeish’s conditions (a) and (b) apply under the Lindeberg condition $\sum_{i=1}^{r_n(\xi_i)} \mathbb{E}[\tilde{W}_{ni}(u, \pi) \times I(|\tilde{W}_{ni}(u, \pi) > \varepsilon)] \to 0$ for any $\varepsilon > 0$. Since $r_n(\xi_n) \leq r_n(1)$, and $r_n(1)g_n \sim n(1) \leq n$, for any $\varepsilon > 0$ it follows

$$r_n(\xi_n) \times \max_{i \geq 1} \mathbb{E}[\tilde{W}_{ni}(u, \pi)||\tilde{W}_{ni}(u, \pi) > \varepsilon|]$$

$$\leq r_n(1) \times \max_{i \geq 1} \mathbb{E}[\tilde{W}_{ni}(u, \pi)||\tilde{W}_{ni}(u, \pi)|^2|]\leq 1$$

$$\leq r_n(1) \times |\pi|\varepsilon^{-1} \max_{i \geq 1} \sup_{u \in [0,1]^{i-1}} \|W_{ni}(u)\|_2 \sup_{u \in [0,1]^{i-1}} \|W_{ni}(u)\|_2$$

$$\leq K \times r_n(1) \times g_n^2 \sup_{u \in [0,1]^{i-1}} \|X_n(u)\|_2 \sup_{u \in [0,1]^{i-1}} \|X_n(u)\|_2$$

$$= O(r_n(1)g^2n^{-a(2)}) = O(g^2n^{-a(2)}) = O(1).$$

The first inequality is Hölder’s and Markov’s; the second and third are Jensen’s and Minkowski’s; and the last line follows from the definition of a functional array and $g_n = o(n^{-a(4)}a(2)^{-1/2})$. The Lindeberg condition is therefore satisfied which completes the proof. □
Proof of Lemma A.3. Define for each element \( \theta \in \{ \xi, u_1, \ldots, u_{k-1} \} \)
\[
w^\prime_0(X_n, \delta) := \sup_{\theta_1 \in \theta \in \theta_2 \in \delta} |X_n(\cdot, \theta) - X_n(\cdot, \theta_1)| \wedge |X_n(\cdot, \theta) - X_n(\cdot, \theta_2)|.,
\]
\[
w_0(X_n, \delta) := \sup_{\delta \leq \theta' \leq \theta + \delta} |X_n(\cdot, \theta) - X_n(\cdot, \theta')|.
\]
According to Proposition 1 of Hill (2007a), cf. Bickel and Wichura (1971) and Neuhas (1971), it suffices to show for every \( \epsilon, \eta > 0 \) there exists a \( \delta \in [0, 1] \) and \( n_0 \in \mathbb{N} \) such that
\[
P(w^\prime_0(W_n(\xi), u, \delta) > \eta/k) \leq \eta/k, \quad n \geq n_0,
\]
\[
P(w_0(W_n(\xi), u, \delta) > \eta/k) \leq \eta/k, \quad n \geq n_0, \quad i = 1 \ldots k - 1,
\]
and for any \( \epsilon > 0 \)
\[
\lim_{\delta \to 0} P(|W_n(\xi) = 1, \cdot) - W_n(\zeta = 1 - \delta, \cdot)| > \epsilon),\]
\[
\lim_{\delta \to 0} P(|W_n(\cdot, u_i = 1) - W_n(\cdot, u_i = 1 - \delta)| > \epsilon), \quad i = 1 \ldots k - 1.
\]
Lemma A.3.1 and the property (cf. Billingsley, 1999)
\[
w^\prime_0(W_n(\xi, u, \delta) \leq w_0(W_n(\xi, u, k\delta), \delta \in [0, 1/k]
\]
implies (23), and Lemmas A.3.2 and A.3.3, respectively, establish (24) and (25).
Finally, Lemma A.3.1 and Theorem 2 of Wichura (1969) ensure \( P(W(\cdot, u) \in C[0, 1]) = 1 \). If condition (g) of Lemma A.1 holds then Lemma A.3.4 guarantees \( P(W(\cdot, u) \in C[0, 1]^{k-1}) = 1 \). □

Lemma A.3.1. For each \( \epsilon, \eta > 0 \) there exists some \( \delta \in [0, 1/k] \) and \( N_0 \in \mathbb{N} \) such that \( P(w_0(W_n(\xi, u), \delta) > \eta/k) \leq \eta/k \forall n \geq N_0. \)

Proof. Drop the argument \( u \) and write \( W_n(\xi) = W_n(\xi, \cdot) \) and \( W_{n,i} = W_{n,i}(u) \). Let \( Z \sim N(0, 1) \) and \( \kappa \geq 1 \) be chosen below. Choose any
\[
\lambda > \max(\epsilon/\sqrt{2}, 2k^2 \times E[Z]^3 \times \kappa/\eta \gamma^2)
\]
and fix
\[
\delta = \frac{\epsilon^2}{\kappa 2 \kappa \lambda^2} \leq \frac{1}{k}.
\]
We can always find a sequence of positive integers \( \{r_n(\xi)\} \) satisfying \( 0 \leq [\delta r_n(\xi)] \leq r_n(\xi) + \delta \) and \( 0 \leq r_n(\xi) \leq n(\xi) \) such that
\[
P \left( \sup_{\xi \leq \xi \leq \xi + \delta} \left| W_n(\xi') - W_n(\xi) \right| > \lambda \nu_n \right) \leq P \left( \sup_{1 \leq j \leq [\delta r_n(\xi)]} \left| \sum_{i=1}^{r_n(\xi) + j} W_{n,i} - \sum_{i=1}^{r_n(\xi)} W_{n,i} \right| > \lambda \nu_n \right)
\]
\[
\leq E \left| \sum_{i=r_n(\xi) + 1}^{r_n(\xi) + [\delta r_n(\xi)]} W_{n,i} \right| \nu_n \right| 3 \lambda^{-3},
\]
where \( \nu_n := \| \sum_{i=r_n(\xi) + 1}^{r_n(\xi) + [\delta r_n(\xi)]} W_{n,i} \|_2 \), and the second inequality is Kolmogorov's. By construction
\[
\frac{E[Z]^3}{\lambda^3} \leq \frac{\eta \gamma^2}{\kappa 2 \kappa \lambda^2} = \frac{\eta \delta}{k}
\]
and from Lemma A.2 for some standard normal \( Z \)
\[
\sum_{i=r_n(\xi) + 1}^{r_n(\xi) + [\delta r_n(\xi)]} W_{n,i} / \nu_n \d Z.
\]
Thus, there exists a sufficiently large $N_0$ such that $\forall n \geq N_0$

$$E \left[ \left| \sum_{i=r_n(\zeta)+1}^{r_{n+1}(\zeta)} W_{n,i} |u_n| \right|^3 \right] \leq \frac{\eta \delta^2}{\lambda^2 2k^2 K} = \frac{\eta \delta}{K} \leq \eta \delta.
$$

(27)

Now, by condition (e) of Lemma A.1 and the martingale difference property of $(W_{n,i}, \mathcal{F}_{n,i})$, for some finite $k \geq 1$

$$v_n^2 = E \left( \sum_{i=r_n(\zeta)+1}^{r_{n+1}(\zeta)} W_{n,i} \right)^2 = \sum_{i=r_n(\zeta)+1}^{r_{n+1}(\zeta)} E(W_{n,i})^2 \leq \delta \times \kappa.$$

Hence, for sufficiently large $N_0$ and all $n \geq N_0$, and $\delta = \epsilon^2/[k^2 2k^2 K^2]$, we have $\lambda \nu_n \leq \lambda \delta^{1/2} K^{1/2} = \epsilon/k$. The claim now follows from (26)–(27): $P(W_n(\zeta, u, \delta) > \epsilon/k) \leq P(\sup_{\zeta \leq \zeta_0} \nu_n(\zeta) - W_n(\zeta) > \lambda \nu_n) \leq \eta \delta \forall n \geq N_0.$

\textbf{Lemma A.3.2.} There exists for every $\epsilon, \eta > 0$ some $\delta \in [0, 1/k]$ and $N_0 \in \mathbb{N}$ such that $P(W_n(\zeta, u, \delta) > \epsilon/k) \leq \eta/k \forall n \geq N_0$.

\textbf{Proof.} Write $W_n(u_j) = W_n(\zeta, \{u_1, \ldots, u_j\})$ and let $0 \leq u_{1,j} \leq u_{2,j} \leq u_{3,j} \leq 1$. By condition (f) of Lemma A.1 and $r_n(\zeta) = \lfloor n(\zeta)/\eta_n \rfloor$

$$E[|W_n(u_{1,j}) - W_n(u_{2,j})| | W_n(u_{2,j})] = \|W_n(u_{1,j}) - W_n(u_{2,j})\|_2 \leq \|W_n(u_{1,j}) - W_n(u_{3,j})\|_2 \leq \eta_n \sum_{i=1}^{r_n(\zeta)} \|W_n(u_{i,j}) - W_n(u_{i,j})\|_2$$

$$= |u_{2,j} - u_{1,j}|^{1/2} \times |u_{3,j} - u_{2,j}|^{1/2} \times O(r_n(\zeta)/\eta_n/n) \leq K \times |u_{3,j} - u_{1,j}|.$$

\textbf{Lemma A.3.3.} For every $\epsilon > 0$, $\lim_{\delta \to 0} P(|W_n(\zeta = 1, \cdot) - W_n(\zeta = 1 - \delta, \cdot)| > \epsilon) = 0$ and $\lim_{\delta \to 0} P(|W_n(\cdot, u_j = 1) - W_n(\cdot, u_j = 1 - \delta)| > \epsilon) = 0$, $j = 1 \ldots k - 1$.

\textbf{Proof.} Use conditions (e) and (f) of Lemma A.1 to deduce

$$P(|W_n(\zeta = 1, \cdot) - W_n(\zeta = 1 - \delta, \cdot)| > \epsilon) \leq \epsilon^2 \times \sup_{i \geq 1} \|W_n(u_i)\|_2^2$$

$$\leq \epsilon^2 \times \|r_n(1) - r_n(1 - \delta)\|_2^2$$

$$\leq K(r_n(1) - r_n(1 - \delta)^2 \to 0$$

as $\delta \to 0$ since $r(\cdot) = \lfloor n(\cdot)/\eta_n \rfloor$, and $n(1) = n(1)$. Finally, (f) and Chebychev’s inequality imply for any $j = 1 \ldots k - 1$.

$$P(|W_n(\cdot, u_j = 1) - W_n(\cdot, u_j = 1 - \delta)| > \epsilon) \leq \epsilon^2 K \times \delta.$$

\textbf{Lemma A.3.4.} Let $v_{jn} := \|\sup_{u_{1,j} \leq u_{2,j} \leq u_{1,j} + \delta} |W_n(\cdot, u_{1,j}) - W_n(\cdot, u_{2,j})|_2 \geq v_j > 0$ uniformly in $n$. There exists for every $\epsilon, \eta > 0$ some $\delta \in [0, 1/k]$ and $N_0 \in \mathbb{N}$ such that $P(W_n(\zeta, u, \delta) > \epsilon/k) \leq \eta \delta \forall n \geq N_0$.

\textbf{Proof.} For large $K > 1$ choose any $\lambda > \max(\epsilon/[2k^2 K^2], K^2/\eta^2 \nu_n^2)$ and $\delta = \epsilon^2/[2k^2 K^2] \leq 1/k$. Condition (g) of Lemma A.1 and Chebychev’s inequality imply $\lambda \nu_n \leq \lambda K^{1/2} \delta^{1/2} = \epsilon/k$ and

$$P\left( \sup_{u_{1,j} \leq u_{2,j} \leq u_{1,j} + \delta} |W_n(\cdot, u_{1,j}) - W_n(\cdot, u_{2,j})| > \lambda \nu_n \right) \leq E\left( \sup_{u_{1,j} \leq u_{2,j} \leq u_{1,j} + \delta} |W_n(\cdot, u_{1,j}) - W_n(\cdot, u_{2,j})| \right)^2 \times \lambda^2 \nu_n^2$$

$$\leq \frac{K \delta}{\lambda^2 \nu_n^2} \leq \eta \delta.$$
Proof of Lemma A.4. Claim (i): Recall $F_{n,t} = \sigma(E_{n,t} : \tau \leq t)$ where $E_{n,t}$ is $\sigma(\varepsilon_{n} : \tau \leq t)$-measurable. Under Assumption 1(b) if $\varepsilon_{i}$ is F-strong mixing with coefficients $c_{ij}$, then $E_{n,t}$ is strong mixing, hence Theorem 17.5 of Davidson (1994) implies

$$\|X_{n,t}(u) - E[X_{n,t}(u)F_{n,t}|\xi_{t}]\|_{2} \leq \max\{\|X_{n,t}(u)\|_{1}, d_{n,t}(u)\} \times \max(b_{n}^{1-1/2}, \phi_{n})$$

By assumption $\|1/2 - \alpha(r)/2\|_{r}^{1/2} c_{ij} = o(1)$, sup $\sup_{i>1}^{\omega(1)} \|X_{n,t}(u)\| = O(n^{-\alpha(r)})$, sup $\sup_{i>1}^{\omega(1)} d_{n,t}(u) = O(n^{-\alpha(r)})$, and $\phi_{n} = o(n^{-\alpha(r)} - 1/2)$ where $\alpha(2) = \frac{1}{2}$ under the functional array definition. We may therefore write for sufficiently large $K > 0$

$$\|X_{n,t}(u) - E[X_{n,t}(u)F_{n,t}|\xi_{t}]\|_{2} \leq (K \times n^{-1/2}) \times \max(b_{n}^{1-1/2}, n^{-\alpha(r)} \phi_{n})$$

say, where sup $\sup_{i>1}^{\omega(1)} c_{ij} = O(n^{-1/2})$ is trivial and $\psi_{n} = o(n^{-1/2})$ follows from $n^{1/2 - \alpha(r)/2} c_{ij} = o(\lambda_{n}^{1/2})$ where $\lambda = r/2 - 2$ and $n^{1/2 - \alpha(r)} \phi_{n} = o(\lambda_{n}^{1/2})$. A similar argument holds for the remaining mixingale bound $\|X_{n,t}(u) - E[X_{n,t}(u)F_{n,t+1}|\xi_{t}]\|_{2} \leq c_{n}(u)\psi_{n+1}$ and in the F-uniform mixing case (cf. Davidson, 1994, p. 265).

Claim (ii): An identical argument applies to $\Delta_{n,t}(u_{1}, u_{2})$. Since the $L_{2}$-NED constants of $\Delta_{n,t}(u_{1}, u_{2})$ are $d_{n,t} \times \max_{1 \leq i \leq k-1}(2|2 - 1/2|, 1)$, the mixingale constants are $c_{n,t} \times \max_{1 \leq i \leq k-1}(2|2 - 1/2|, 1)$ for some sup $\sup_{i>1}^{\omega(1)} c_{ij} = O(n^{-1/2})$.

Claim (iii): $\limsup_{n \to \infty} \sup_{u \in [0,1]} \left| \sum_{j=1}^{n} \left( \sum_{i=1}^{j} \rho_{i} \phi_{i} \right) \right|^{2} - 1 \leq 0$ for any sequence of points $\{\xi_{n}, u_{1}\}_{n=1}^{\infty}$ follows from Lemmas A.5 and A.6 and an argument identical to de Jong’s (1997, A.39–A.41).

Proof of Lemma A.6. Because $u \in [0,1]^{k-1}$ and $\varepsilon \in [1, \varepsilon]$ are arbitrary, the claim follows from Lemma A.4 of Hill (2005). □
